**Zhubanyshev Alisher - Friday 9AM(14-N)**

**Shayakhmetov Nurzat - Saturday 10AM(07-N)**

**Key words:** education, inequality, language of education, segregation among schools, students' performance, university performance.

## **Abstract**

In this research, we are wondering which factors might affect students' success in university. Most recent studies focus mostly on short-term results such as performance in high school. We decided to investigate these factors in the long-term run, taking the factors in schools that might affect a person in the future university. The results were approving and disapproving some stereotypes that we had before the research.

## **Introduction**

The education system in Kazakhstan determines the future of the country. That is why society is so closely watching, having a lot of discussions and arguments on the theme of school education in the Republic of Kazakhstan. We always

hear a bunch of school stories from lots of people and they of course include stories about the education process itself. Some graduated from lyceum, while others finished ordinary schools. Both in one city, in one period of time. Their memories and experiences from school courses regularly differ. Parts of them recall how there were laboratory experiments in exact studies such as chemistry and physics. They also remember most of read books in literature, and what they were about. When it comes to the other part of alumni, they can not say the same. Maybe they just were not that attentive to the course program, but anyway, according to that we can say that the education process varies even in the area of one city. So we got curious about this topic. Where teaching is better or worse. And can school background have any kind of effect on further university or college life of a student?

## **Literature review**

The first article [1] one of us found is related to the languages of education in Kazakhstan, namely, education in Russian and Kazakh languages. We were wondering what factors at school affect a student's academic performance at university so our team searched for possible reasons and looked through articles in which the authors assumed such reasons. All of us have carefully read these articles, trying to understand the author's perspective, analyze these reasons and identify our point of view: do we agree with these reasons or not, what can be mistaken in other studies, what options can we offer that will be more useful for our research, etc.

Website of the Kazakh Service of the International Media company Radio Free Europe/Radio Liberty, AZATTYQ RYHY [1], relying on the opinions of experts, gives us the answers to the following questions: Does studying in these two different languages affect the quality of education in the country? And if it does, then how?

AZATTYQ RYHY claims that recently Kazakhstanis have a greater tendency to receive education in Russian, especially in the northern part of the country. The National Center for Education Quality Assessment of the Ministry of Education and Science of the Republic of Kazakhstan has published a detailed report on the results shown by 15-year-old Kazakhstani students during the PISA (Program for International Student Assessment) tests, which our country

also covered for the first time. PISA is a program of international research of educational achievements of students. The results of the tests revealed a serious gap between the level of knowledge and skills of students of Russian and Kazakh classes in favor of students of Russian classes. Also, in terms of books, documentaries and other sources of useful information, we have more such resources in the Russian language.

We can learn more about this from the following article 'Why Language of Education is One of the Factors of Educational Inequity' [2].

As FORBES.KZ mentioned, currently, from a linguistic point of view, the Kazakh language prevails in the education system, but the quality of teaching in it causes concern among experts and they consider the lack of high-quality textbooks to be one of the main reasons for the unsatisfactory situation. Considering all these we can take the language of education as one of the reasons that affect a student's academic performance.

Let's consider the following article 'Why Kazakhstani Pupils Failed International Examination PISA' [3].

In this article FORBES.KZ examines the main achievements of Kazakhstan in PISA and the main reasons for the backlog of Kazakhstani schoolchildren relative to schoolchildren of other countries. PISA touches on the socio-economic status of parents of schoolchildren. In the latest PISA-2018 study, it was revealed that in Kazakhstan, socially and economically prosperous pupils outperformed disadvantaged pupils in reading by 40 points. We agree that the socio-economic status of parents can affect the educational process of a child. Parents who earn well, as a rule, have a good education, which may affect the availability of books in the house or the child's greater interest in knowledge. Besides, wealthy parents can hire tutors for their children, which can also affect the learning process for the better. The article also touches on the problem of the Internet in schools.

The international studies of 2018 PISA, PIRLS, and the crisis that has overtaken all of us have shown the real possibilities of tele-communication technologies in Kazakhstan. In this connection, the Ministry of Education was forced to abandon online education. Also there was a difference in the results between genders. From here we can take tutors, gender, internet at school, salary of

parents, education of parents as the reasons that affect a student's academic performance.

Let's move to the next article we picked 'Income Segregation between School Districts and Inequality in Students' Achievement' [4].

Here we can see that Ann Owens, the author of the article, shares her thoughts about how educational inequalities between high-income and low-income children have grown in recent decades, confirmed and consolidated by the results of tests conducted at different times.

From the variants that have not been considered, we can highlight several options in this article. According to her, race greatly affects the quality of education. We know that racism has taken place in many countries, it is terrible and unfair, but recently, after so many years of fighting racism and inequality, we can observe that the situation is slowly, but still changing for the better. If we consider Kazakhstan, then everyone here has the right to study at school and get a higher education(at least according to the legislation). If we look at it only from this point of view, then we can carefully but surely not consider race as one of the reasons in our research. Also Ann Owens mentions studying in remote localities, like villages, mentions to us about conditions that are usually worse than in developed cities. Just wanted to remind that in Kazakhstan, there is a shortage of books in schools in developed cities and the Internet in cities needs to be improved, we can only imagine conditions in remote villages. From here we can take the place of study (village\city) as the reasons that affect a student's academic performance.

The next article is "The Factors Influencing Students' Performance at Universiti Teknologi MARA Kedah, Malaysia"[5].

Students in Malaysia did research on almost the same topic. The researchers found that four factors are positively related to students' performance that are demographic, active learning, students' attendance and involvement in extracurricular activities.

Many extracurricular activities have proven to be beneficial in building and strengthening academic achievement, even if the activities are not obviously related to academic subjects.

Participation in extracurricular activities in general, is associated with an improved grade point average, higher educational aspirations, increased college

attendance, and reduced absenteeism. Taking this into account, we decided to add to our research several options such as sports, art classes as the reasons that affect a student's academic performance.

We also found 5 more articles that consolidate the positions of the reasons that we have already chosen above [6], [7], [8], [9], [10].

We are the first team that decided to check whether there is a connection between school performance and university performance, so we added several options to make the results of our research more accurate.

### **Design of research**

In order to find out what factors at school affect a student's academic performance at university we have done an experiment. We have created a questionnaire for students. We have added questions to this questionnaire based on articles that in our opinion had an affect on the student's performance. First of all, we asked the students their gpa, because gpa is an objective indicator of a student's success. Since our country, Kazakhstan, is a multinational country, accordingly we have many nations and languages. One of the articles considered which schools do parents prefer [1]. Most of the students in the country are taught in two languages. These are Russian and Kazakh languages. There are also students studying other languages. These are Uighur, Uzbek, Tajik and so on. But they are a minority. The article examines which school graduates are more educated. According to the results of the study, the Russian classes are more educated. This is the result of 2011. We were interested in whether things are the same now. That's why we asked the students in what language they studied. Since we conducted the research in Kazakhstan, we mainly relied on articles that are related to Kazakhstan. One of these articles is a FORBES article about the international PISA program [3]. This article discusses the results and factors that affect the education of schoolchildren. Here we noticed some interesting facts. Girls scored more points than boys. That is, gender can also influence education. The Internet in schools is mentioned here. About 90 percent of schools are provided with the Internet, but their quality is poor. This means that not all schools have good Internet. We thought that the presence of the Internet can also affect academic performance. We have

included a question about the Internet in schools in the questionnaire. The education of parents and their economic condition and whether their children go to the tutor are also considered. We have also added questions about these factors.

In the article "The division of income between School districts and Inequality among students Achievement" [4]. The inequalities of American students are considered. Here we are talking about children in high-income and low-income families and their race is mostly white or black. The author explains how these factors affect the education of children. Unfortunately, we were not able to include these factors in our questionnaire because we do not have a social problem by race. And the well-being of the family is difficult to determine through a questionnaire. But we may have a problem with the difference in education between the village and the city. And we added a question about the place of school.

Our topic is what factors at school affect a student's academic performance at the university, so it is logical to assume that the average grade in school subjects will play at least some role, so it is the first option from our team.

As we know, there are many schools in Kazakhstan such as BIL, NIS, RPhMS, it is interesting how graduates of these schools prove themselves at the university, so the second option is from which of these BIL/NIS/RPhMS schools was a student.

In addition to these schools, there are others that are divided into ordinary, gymnasiums and lyceums. There are also private schools, so we added gymnasiums/lyceums/ordinary/private schools as options.

We also assumed that knowledge of English would facilitate the student's academic activities. Therefore, we added the level of English language proficiency to the list of options.

With all these options, we conducted a survey among students of several universities, processed the data and obtained the following results.

## Data and Methods

74 students took part in our survey, and only 69 results were counted as valid. All of them are students of 2,3 and 4 courses from different universities of Kazakhstan, such as Suleyman Demirel University, Kazakh-British Technical University, Nazarbayev University and Almaty Management University.

As it was mentioned above in research design part, we asked our respondents not only their GPA of first semester, but also their gender, place of living, language of school they attended, form and type of school, whether they were busy with extra lessons, sport or art hobbies, Internet availability at school, their English level by the end of high school, their school performance, parents' income and parents' education.

In the following sections we want to describe our respondents.

Fig.1 Regarding gender, 46 were male, and 23 were female, which is 66.7% and 33.% respectively. By place of living we have 57 town folks and 12 village residents. More people were studying in Kazakh than in Russian: 37 versus 32. For school type in Fig.2. we had Gymnasium/lyceum attended 29, ordinary schools - 22, NIS/BIL/RPhMS - 17 and private schools (like Miras or Galaxy) only 1. Which is surprising, since 8 people thought they attended private school, and other 61 attended state schools.

Fig.1. Gender, place of living and language of school distributions.

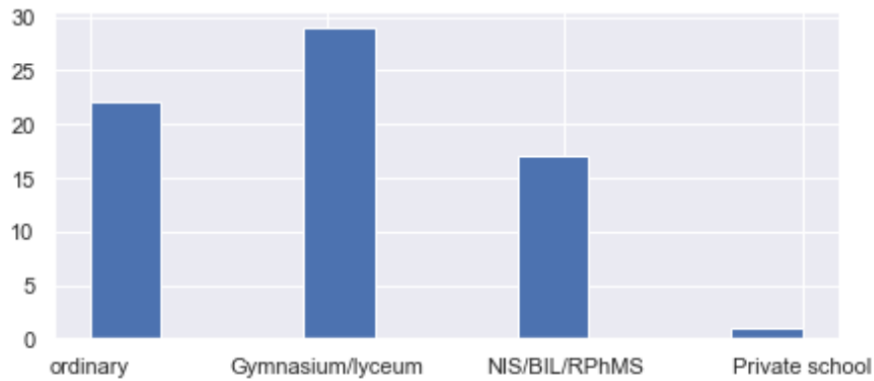

Fig.2. Type of school distribution.

Fig.3. Type of property of school distribution.

Roughly equal proportion were attending private tutors and were not: 34 for 'yes' and 35 for 'no'. A bigger difference was for sports: 30 people were going to sport clubs whereas 39 were not. In the art section (like painting, theatre, handwork) only 27 were interested, while the other 42 were not. So as we see, having extra lessons beyond schooling is more popular than having non-educational hobbies.

Surprisingly, 45 people had internet at school, 24 did not.

School performance: 34 and 32 had Good and Excellent performance respectively, only 3 had Satisfactory marks.

Fig.4. School performance distribution.

We had a very wide distribution in English level: A0-A1 level had 14 students, A2 - 9 people, B1 and B2 both had 19, and C1-C2 - 8.

Fig.5. English level distribution.

Since parents' state could have a huge impact on students, we also asked about their education and average wage (see Fig.6. and Fig.7.). Most parents had higher education (60 vs 9) and the most common wage was in the range 200 000 - 300 000 tenge.

Fig.6. Parents' education: 'yes' if at least one parent had college diploma, 'no' if none of parents attended college.

Fig.7. Parents' income during high school.

Now, after we described all the data we had, we try to estimate which of these characteristics of school past can affect future performance in university.

In statistics we have several tests to estimate which parameters have the most weight on our dependent variable (GPA in university in the first semester).

First test is the P-values test. We will apply the 5% cut-off rule, which means that parameters with p-values less than 0.05 (5%) are more statistically significant.

Here is Table 1 with coefficients and p-values. As we see, such variables as English at B2, English at C1-C2, Excellent and Good performance at high school are statistically significant for GPA in university.

	coef	std err	t	P> t	[0.025	0.975]
const	1.9513	0.312	6.248	0.000	1.324	2.579

gpa_school_Satisfactory	0.4778	0.368	1.300	<u>0.200</u>	-0.261	1.216

Table 1. Coefficients and p-values ( $P>|t|$ ).

Another test, such as Lasso Regression will shrink all insignificant variables to 0, while setting significant ones to proper values greater than 0. On Fig.8. the Lasso test showed that English at A0-A1 and C1-C2 levels, Excellent performance at high school, art and gender are significant. However, art and gender might be misleading since our data is imbalanced, i.e. we have too few females and too few art people. Also, we see that English level and Excellent performance are still meaningful for future GPA at university.

Fig.8. Lasso Regression test shrinks non-significant values to 0.

Third test is to fit the Linear Regression model, which will try to predict Y (GPA at college) looking at data X (all other metrics). It will have the form

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_i X_i$$

Y : Dependent variable  
 $\beta_0$  : Intercept  
 $\beta_i$  : Slope for  $X_i$   
 X = Independent variable

Then we will look at coefficients  $\beta$ 's: the bigger the coefficients (the 'weights'), the more significant the X (the metrics like English level and so on).

After fitting the model we have in Table 2 that Private School, English levels at B2, C1-C2, Excellent performance have more ‘weight’ on future GPA. Also the place of living could affect the performance.

	Coefficient
<b>type_Private school</b>	6.009576e-01
<b>english_C1-C2</b>	5.201947e-01

Table 2. Linear Regression Coefficient in descending order.

The last test to try is Correlation Matrix. A correlation matrix is simply a table which displays the correlation. The measure is best used in variables that demonstrate a linear relationship between each other. As we see in Table 3, GPA is most correlated with Excellent performance at school, English at C1-C2, A2 and B2 levels, having extra lessons with tutors.

gpa	1.000000
gpa_school_Excellent	0.289497
english_C1-C2	0.200991
tutors	0.101124

wage	-0.023771
private	-0.049217
type_NIS/BIL/RPhMS	-0.068411
internet	-0.084145
art	-0.155846
male	-0.169619
gpa_school_Satisfactory	-0.182062
gpa_school_Good	-0.214502
english_A0-A1	-0.271849

Table 3. Correlation matrix shows the correlation for GPA with other variables.

To sum up, all 4 tests showed that students with Excellent performance at school, English at a very good level will boost the student in university. Other variables that some tests showed were attending Private schools, tutors, place of living and art hobby.

P-value test	Lasso Regression test	Linear Regression test	Correlation Matrix
English B2 English C1-C2 Excellent at school Good at school	English A0-A1 English C1-C2 Excellent at school Gender Art	English B2 English C1-C2 Excellent at school Private school Place of living	English B2 English C1-C2 English A2 Excellent at school Tutors

Table 4. Comparing the results from different statistical tests.

## Results

Excellent students might have better GPAs at college thanks to good time management acquired at school. English at a high level is a good instrument at college with programs in English. Other factors that appeared in tests (Private schools, tutors, place of living) could be caused by parents' income, which we can test too.

Let's look at average GPA among Excellent, Good and Satisfactory marks at school. As we see, A-students have higher GPA than other groups (3.16 average GPA for Excellent, 2.81 for Good and 2.39 for Satisfactory). So we can conclude that performance at school can affect university performance significantly.

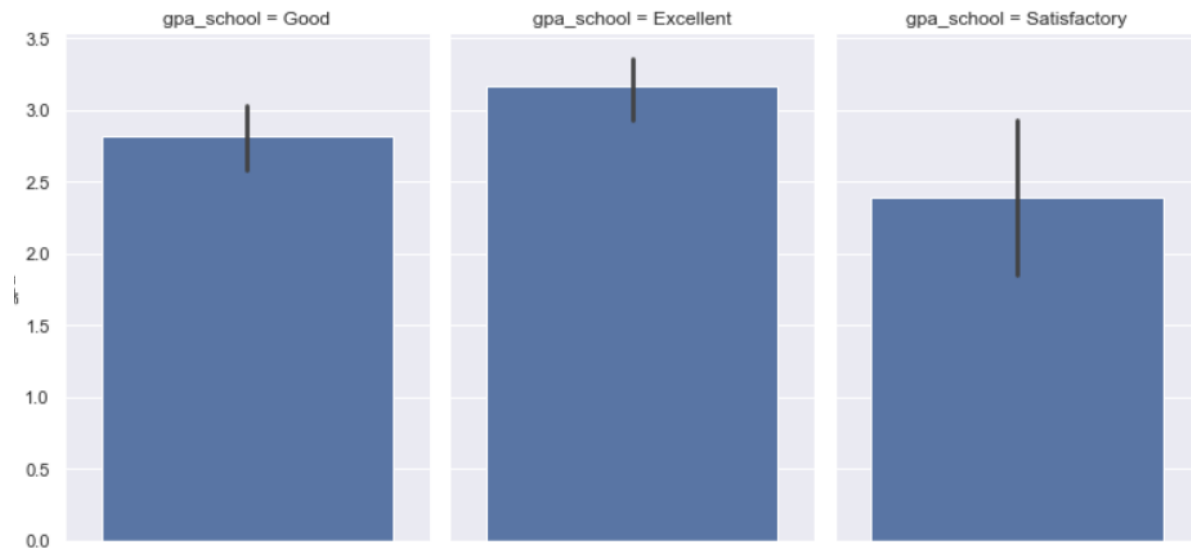

Fig.9. GPA dependence on school performance.

Let's compare GPA among English levels. We again see a strong link between level and GPA: people with level at C1-C2 have higher GPA (3.32) and people with English at level A0-A1 have the lowest GPA (2.6 on average). So, the significance of the English level is proved.

Fig.10. GPA dependence on English level.

One of the tests also showed the significance of the type of school. We cannot conclude a strong relationship, since we had only 1 respondent who chose ‘Private school’ type. Moreover, NIS/BIL/RPhMS showed lower GPA than students from ordinary and gymnasium/lyceum schools.

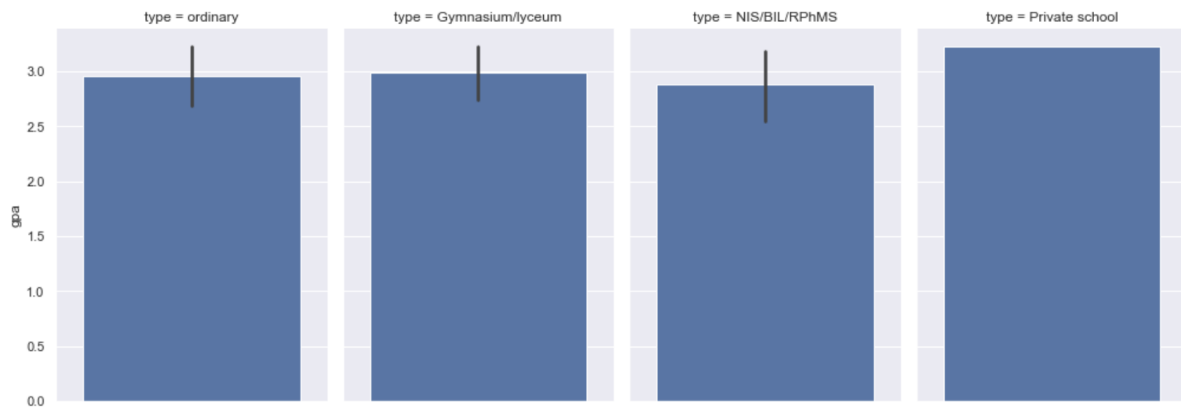

Fig.11. GPA dependence on school type.

Another test showed the significance of having private tutors. Here tutors really could improve a student's future performance (2.89 vs 3.02 average GPAs).

Fig.12. GPA dependence on having private tutors at school.

Another test showed the significance of gender. Indeed, girls have a higher GPA (3.11) than boys (2.88).

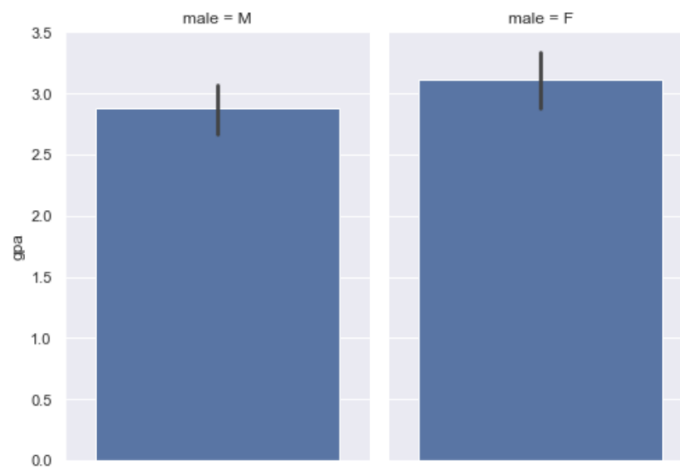

Fig.13. GPA dependence on gender.

What is interesting, art hobbies were affecting GPA in the opposite way: art people had a lower GPA (2.82) than other people (3.03). Maybe art people were spending more time on their professionalism in art than in their college studies.

Fig.14. GPA dependence on attending art classes.

Even though our tests (p-values, Lasso Regression, Linear Regression and Correlation matrix) did not highlight other metrics as significant, we decided to check all metrics to find interesting correlations.

For example, in the beginning of the article we were referring to AZATTYQ RYHY article [1], that parents were giving their children to Russian classes rather than to Kazakh, since there are some prejudices about the quality of education in Kazakh language. As we see, average GPAs are roughly on the same level (2.94 and 2.97 for Russian and Kazakh schools). After further study it can be proved that the language of school does not really affect pupils' future performance.

Fig.15. GPA dependence on the language of studies in school.

We also see that place of living did not cause a big difference in GPA for city and village (2.95 and 2.97 on average). However, the village has a greater deviation, thus not as stable as the city in GPA.

Fig.16. GPA dependence on place of living.

Another interesting correlation showed sports: people who were participating in sport classes were more successful than those who did not (2.99 vs 2.92). Maybe in the further investigation, we will see either a good effect on students' health and thus better grades, or that sport trains discipline in students.

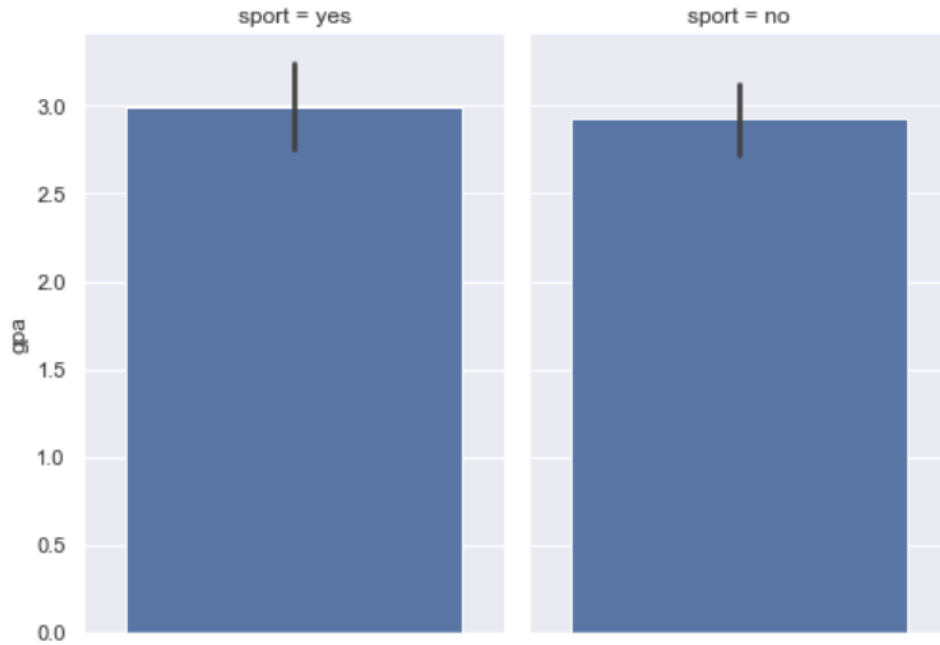

Fig.17. GPA dependence on sport.

We also cited an article in the beginning [4] that parents' status may affect school performance. As we already noticed, school performance affects college GPA, so we tried to see the correlation between parents' status and GPA at college. As we see, if at least one parent had higher education, the student's GPA was slightly higher (2.96) than those whose parents did not attend college (2.93). However, GPA is more stable for those whose parents had diplomas, whereas GPA for non-diploma parents fluctuates drastically.

Fig.18. GPA dependence on parents' education.

As we see on the graph, students whose parents' income was in the range of 400 000 - 500 000 had GPAs a bit higher than others on average. However, it does not grow linearly: students with house income 500 000 and more perform less on average. So we cannot conclude a strong link between parents' wages and students' future grades, as we were suspecting at the beginning of the article [4].

Fig.19. GPA dependence on parents' income.

## Conclusion

In our survey, 74 students from different universities of Kazakhstan participated. Our goal was to find out what kind of factors from school influence university success.

We used our knowledge in IT technologies to collect data and make a conclusion from them in the form of mathematical formulas.

The results were interesting, we found out the type of school was not important, that on average all students no matter from what kind of school they came from, have approximately the same GPA. The interesting thing that we found out is that GPA is not dependent on the language of school. Also, we do not find a big difference in GPA of students from village and city, but little preponderance among students who are interested in sport, compared to students who are not interested. Thus we disapproved some prejudices about the abilities of students from that or another school.

The main factors that impacted the success in college were knowledge of English and performance in school: A-students could adapt better for high load in university, thus achieving better grades.

By gender, we find out that there is little overweight GPA for women. Their interest in art is also slightly overweight to people who are not interested in art.

But in fact of the salary of parents, we find out that the higher GPA has students whose parents have a salary above 200-300 thousand tenge. So concluded, that assumption in the article [4] that parents' status has an effect on students' success is valid for our situation.
